

Title: **Documentation for AVR J1850 VPW Interface**

Issue: F

Author: Michael Wolf

Printed: 22/10/2005

Overview

AVR J1850 VPW interface to connect a Chrysler or GM car bus to a PC for On Board Diagnostic (OBD) monitoring. My interface is build around Atmel AVR mega8 controller, my favourite "workhorse". The controller is available also in DIP package for all who not want to built with SMD components. With 8k flash memory we have plenty of space for all kind of features. The basic source code which supports all functions uses 3k code space.

Some features:

- SAE J1850 VPW to RS232 interface
- simple AT command control
- different Baud rates, from 9600 to 115200 Baud
- 4 different bus monitor functions
- support for 1 and 3 byte header messages

The source code for this interface is released under GNU GENERAL PUBLIC LICENSE.
See license.txt for details.

Hardware description

The circuit is designed for a single layer PCB.

K1	VPW bus connector Pin 1 = Ground Pin 7 = VPW bus In/Out Pin 9 = 12V supply
K2	RS232 serial connector Pin 2 = Serial out Pin 3 = Serial in Pin 5 = Ground
K3	In-Circuit-Programming connector Compatible pin-out for Atmel STK500 development board Pin 1 = MISO Pin 2 = 5V supply Pin 3 = SCK Pin 4 = MOSI Pin 5 = Reset Pin 6 = Ground
IC1	5V fixed voltage converter to supply the uC and RS232 converter
D1	Power on indication
D2, T1	VPW bus traffic indication, incoming and outgoing
T2	VPW input buffer, signal inverter and voltage converter
D3, D4, T3, T4	VPW output buffer, signal inverter and voltage converter
IC2	main controller
IC3	RS232 level converter

Note:

Firmware version 1.04 and higher requires a crystal with 7.3728MHz for proper function.

Important note:

**The voltage regulation circuit R8/D4 is designed for at least 315 Ohm bus load!
Do not keep the J1850 line in high level without load resistor connected to K1-7 and K1-1 otherwise D4 will be destroyed immediately.**

Programming the AVR

The circuit provides an ISP connector to program the firmware. Use your favourite programming hardware to flash the AVR.

After flashing the firmware you must change the fuse settings on new devices. Remember that a “clean” ATmega8 is delivered with internal RC oscillator enabled, running at 1MHz.

Program (checked) the fuses in the following order:

In AVR-Studio:

- Boot flash section size=128 words Boot start address=\$0F80; BOOTSZ=11
- Brown-out detection level at VCC=4.0V; BODLEVEL=0
- Brown-out detection enabled; BODEN=0
- CKOPT fuse; CKOPT=0
- Ext. Crystal/resonator High Freq.; Start-up time: 1k CK + 0ms; CKSEL=1110 SUT=10

All other fuses are not used.

In PonyProg:

Checked fuses:

SUT1, CKSEL0

Unchecked Fuses:

BOOTSZ1, BOOTSZ0

Leave the rest untouched!

Configuration and Security bits

☐ 7 ☐ 6 ☐ BootLock12 ☐ BootLock11 ☐ BootLock02 ☐ BootLock01 ☐ Lock2 ☐ Lock1

☐ RSTDISBL ☐ WDTON ☒ SPIEN ☒ CKOPT ☐ EESAVE ☐ BOOTSZ1 ☐ BOOTSZ0 ☐ BOOTRST

☒ BODLEVEL ☒ BODEN ☐ SUT1 ☒ SUT0 ☐ CKSEL3 ☐ CKSEL2 ☐ CKSEL1 ☒ CKSEL0

☒ Checked items means programmed (bit = 0) ☐ UnChecked items means unprogrammed (bit = 1)

Refer to device datasheet, please

Cancel OK Clear All Set All Write Read

Communicating with the interface

Communication is done via serial RS232 connection.

Default connection settings are:

9600 (default) or 19200 Baud

8N1 - 8 data bits, no parity bit, 1 stop bit, no handshake

All responses from the interface are terminated with a single carriage return character and, by default, a line feed character as well.

After correct connection and power up, the interface will display the initial message:

AVR-J1850 VPW v1.04

May 10 2005 / 18:33:53

>

Showing code description and version, date and time when the code was compiled and the command prompt character '>'.
The interface is now ready and can receive user commands. All commands used to control the interface are separated from vehicle commands with the command tag "AT". Vehicle commands can contain only with ASCII characters for hexadecimal digits (0-9 and A-F).

All commands send to the interface, internal AT or hex string for VPW, must be terminated with a single carriage return character (0x0D) before they will be accepted, they are not case sensitive.

A single "?" will indicate that the message was misunderstood by the interface (syntax error). This includes wrong or incomplete AT commands and wrong hex strings. This is not a sign for invalid VPW message because the interface not validates VPW message.

AT command description

An interface control command must begin with the "AT" command tag followed by a command code and, if required, one or more parameters.

AR [Automatic Receive address] Default: ON

Set the receive address is equal to the third header byte for physical addressing or second header byte +1 for functional addressing.

The receive address changes whenever the header bytes changes.

Bxx [set Baud rates] Default: 115200 Baud

Set desired Baud rate. The interface will change the Baud rate immediately after executing the command. Status message is returned with new Baud rate set.

Possible values for xx: 0 = 9600 Baud 1 = 14400 Baud
 2 = 19200 Baud 3 = 28800 Baud
 4 = 38400 Baud 5 = 57600 Baud
 Any other value = 115200 Baud

Note: Default Baud rate is configured in file main.h

D [set Defaults]

Set all interface values to default.

E0 or E1 [Echo on/off] Default: ON

With echo on all characters received via RS232 are echoed back to user terminal.

FD [Formatted Data] Default: ON

All responses are returned as standard ASCII characters readable on any terminal program. Hex values are returned as 2 byte ASCII values, separated by space and terminated by carriage return and optional line feed.

H0 or H1 [Header on/off] Default: OFF

Controls whether or not the header and CRC bytes are shown for received VPW messages.

I [Ident]

Returns interface identify string.

L0 or L1 [Line feed on/off] Default: ON

Controls whether or not a line feed character is returned with each carriage return character.

MA [Monitor All]

Set the interface in monitor mode. All message received via VPW bus are returned, optional with header and CRC.

Any serial input will stop this mode and the interface returns to idle state waiting for user inputs.

Note:

You will see garbage output if MA mode is enabled, Header output is disabled and VPW frames are transmitted with one byte header only. Use command AT O1 first to enable one byte header modus for correct output!

MI xx [Monitor ID]

Set the interface in monitor mode for a specific frame ID provided as command parameter. The frame ID is the first byte in J1850 messages in single byte header format, i.e. used in Chrysler vehicles.

All message received via VPW bus matching the given frame ID are returned, optional with header and CRC.

Any serial input will stop this mode and the interface returns to idle state waiting for user inputs.

See SAE J2178-Part 3 for details of frame ID and single byte header format.

MR xx [Monitor Receiver]

Set the interface in monitor mode for a specific receiver address provided as command parameter. All message received via VPW bus matching the given receiver address are returned, optional with header and CRC.

Any serial input will stop this mode and the interface returns to idle state waiting for user inputs.

MT xx [Monitor Transmitter]

Set the interface in monitor mode for a specific transmitter address provided as command parameter. All message received via VPW bus matching the given transmitter address are returned, optional with header and CRC.

Any serial input will stop this mode and the interface returns to idle state waiting for user inputs.

O0 or O1 [One Byte Header on/off] Default: OFF

Use this command to enable or disable transmitting and monitoring of one byte header messages. With this option enabled the interface will send only one byte as header instead of three bytes. The header byte must be set using command AT SH xxyyzz, where xx is the header byte which is will be used. Byte 2 and 3 will be ignored, but must be send to make a valid AT SH command.

In MA mode this command ensures the correct data output if headers are disabled.

PD [Packed Data] Default: OFF

All messages received via VPW bus are returned as hex string starting with a single length byte followed by complete message content, without terminating character (carriage return or line feed).

The length byte will indicate only the number of data bytes following, excluding itself.

If a message error was detected (CRC error) the MSB bit 7 of the length byte is set to indicate an error.

If no data was received within the time out a single length byte with value '0' is returned.

R0 or R1 [Responses on/off] Default: ON

With responses turned off, the interface will not wait for any response from the vehicle. All given VPW messages are passed to the bus and the interface returns immediately to idle state, waiting for user inputs.

With responses turned on, the interface will wait at least 100ms for node response and an additional timeout which is set via ST command.

SH xx yy zz [Set Header]

This command set the three byte header which is send before all user VPW commands.
For details of header bytes see standard SAE J2178 part 1 and SAE J1979.
Default header is 0x68 0x6A 0xF1 for external diagnostic equipment.

SR xx [Set Receive Address]

Users can set a specific receive address to which the interface will respond. This command will turn off AR mode and the interface will accept only responses from address xx.

ST xx [Set Timeout] Default: 50

This command set the additional timeout before the interface returns an "NO DATA".
Default value is 50 which give an additional timeout of $4\text{ms} \times 25 = 100\text{ms}$.
The command parameter must be send as hex value range 0x00 to 0xFF. Values less than 0x08 will be forced to 0x08 to set a minimum timeout of 32ms.
This timeout recommended to the 100ms minimum node response timeout specified in SAE J1850.

Z [Reset]

The interface will perform a complete reset, all values will set to default.

Note:

For commands with 0/1 disable/enable option, only a '0' will disable the function, other values than '0' will enable the function!

ODB or VPW commands

I will not describe VPW or ODB commands here, because you can find a lot of ODB information using your favourite internet search engine and it's not the purpose of this document.

Just a few words how to send VPW messages using the interface:

All VPW messages must be sent as hex string given with 2 byte ASCII values. String length must be an even number of ASCII bytes with a maximum number of 8 VPW data bytes. No header byte (set via SH command) and NO CRC.

CRC will be calculated independent for each given hex string will be included automatically to the message sent to the bus.

So the maximum message length sent to the VPW bus is 12 bytes as specified in SAE J1850.

The interface will calculate a CRC for all messages received via VPW bus. This CRC will be compared with the received CRC. In case of CRC error, the interface will mark this message faulty.

Error messages

The interface will return various error messages; here is a description of each message:

BUSBUSY

The interface tried to send a message but bus was busy.

BUSERROR

The interface has detected a bus error. It was not possible to change bus levels, or a bit level collision was detected.

<DATAERROR

Calculated and received CRC byte not equal, message faulty.

NO DATA

No data received within timeout.

?

Given command wrong or incomplete or hex string wrong or incomplete.

OK

Not an error message, but indicates execution of given command successful.

You will find the interface schematic, PCB layout, part placement layout and bill of material in the appendix of this document.

PCB layout file is available on request. Format will be Target 3001 v11.
